I. Introduction and the Access to Justice Disconnect

In recent decades, third-party interventions have fundamentally transformed constitutional litigation in Canada. As Alarie and Green¹ demonstrated, interveners historically made submissions in roughly half of all cases heard by the Supreme Court of Canada (SCC) between 2000 and 2008.² They also noted that *Charter* appeals were the most intervener-intensive, with a rate of intervention approaching 90% throughout the 1990s and 2000s.³ My own empirical analysis in this project confirms and updates this reality for the modern era: out of 402 *Charter* cases heard by the SCC between 2011 and 2025, 346 cases (86%) featured third-party intervenors.⁴

Why does the SCC allow so many interventions? Alarie and Green posit three main theoretical motivations, *accuracy*, *affiliation*, and *acceptance*.⁵ For public interest litigation, *accuracy* and *acceptance* are particularly relevant: the Court seeks *accuracy* by gathering specialized information, which parties to the immediate dispute might not provide;⁶ and *acceptance* by allowing diverse voices to be heard in order to increase the public legitimacy of its *Charter* decisions.⁷

These statistics reveal that intervention is a core mechanism for shaping Canadian constitutional law at the SCC. However, participating in this process is legally and practically demanding. The intervention process is governed by the *Rules of the Supreme Court of Canada*.⁸ At a minimum, an applicant seeking to intervene must satisfy a strict two-part test: First, the applicant must show that it has an interest in the proceeding; second, the applicant must demonstrate that it will make submissions that are both “useful and different from the parties’ submissions”.⁹ To meet this second criterion, an intervener must leverage its expertise to “shed fresh light or provide new information on the matter”.¹⁰ Because of these technical requirements of intervention, translating a perspective obtained in daily legal practice into a highly technical legal contribution that respects these strict SCC boundaries requires specialized legal representation.

This creates a severe Access to Justice (A2J) paradox, which I observed firsthand while working at a legal clinic: on the one hand, grassroots legal clinics have deep subject-matter expertise and represent marginalized communities. They perfectly possess the “unique perspective” required by the *Workers’ Compensation* test. However, their own workload is always too heavy to intervene by themselves, and they also severely lack financial resources to hire specialized external counsel to draft their factums and appear at the SCC; on the other hand, I interviewed private firm lawyers who frequently engage in constitutional litigation. They have the resources, skills, and desire to perform *pro bono* appellate work in the public interest. However, standing rules generally prevent individual

lawyers from intervening on their own; they need an institutional client to provide the requisite “interest” and “perspective.” Because of a severe information asymmetry, they cannot find each other. This “A2J Charter Intervention Accelerator” project aims to bridge this gap. By scraping and mapping empirical SCC docket data, this project builds a visual network of the existing constitutional litigation ecosystem. The ultimate goal of this project is to reduce barriers to intervention in constitutional litigation; at this stage, the initial objective is to facilitate strategic partnerships between resource-constrained legal aid organizations and willing external attorneys.

II. Methodology

2.1 Data Source

To build an accurate matching tool, this project required high-fidelity data. I engineered a custom web-scraping pipeline using Python and the BeautifulSoup library to extract intervenor and counsel data directly from 402 official SCC docket web pages (from 2011 to 2025). For a detailed discussion on why the HuggingFace a2aj dataset was not used, and for the specific data engineering code, please see *Appendix A*.

2.2 From Raw Data to Visual Analytics

The 402-case dataset required substantial cleaning before it could support reliable analysis. State actors such as Attorneys General were removed, as their near-universal participation would distort any meaningful network analysis. Organization names were also standardized. The cleaned datasets are attached in *Appendix B*.

However, raw data in a spreadsheet is not easily accessible for a busy legal clinic worker or an individual lawyer in a private firm. Therefore, the output of this project in this stage is a suite of visual analytics built on top of this data. These include an interactive HTML bipartite network map, a jurisprudential heatmap, and strategic dashboards. These visual tools are presented in **Section III** below.

2.3 Accuracy Validation and Programmatic Error Handling

To verify the correctness of the dataset, a manual audit of a 30-case randomized sample (2011–2025) was conducted against official SCC online dockets. The accuracy rate turns out to be 96.67%. The single discrepancy occurred in a massive Reference case,¹¹ where the Generative AI (“GenAI”) extraction tool accurately identified the intervening organizations but defaulted to “None listed” for counsel.

After identifying this issue, a comprehensive sweep of the dataset was then conducted for the entire 402 cases. A specific failure mode was found and resolved accordingly. The specific cases affected, the current solution to this issue and proposed future strategies are detailed in *Appendix C*.

III. Visual Analytics and Empirical Findings

¹¹ *Reference re An Act respecting First Nations, Inuit and Métis children, youth and families*, [2024 SCC 5](#) [Re First Nation Children].

With the sanitized dataset, the next objective was to visualize the raw information.

3.1 The Bipartite Network Map: Uncovering the Hidden Ecosystem

The first visualization is an interactive Bipartite Network in HTML format. A bipartite graph is a network that contains two distinct types of nodes, where connections only exist between different types. In this context, the two types of nodes are NGOs (intervenors) and Individual Counsel (lawyers).

See: [Code 3.1](#) at Jupyter Notebook *Final Code_Chong Tan.ipynb*

See full HTML page: [A2J_Counsel_NGO_Map.html](#)

In the visualization, NGOs are represented as green circular nodes, while individual counsels are represented as red triangular nodes. The size of each node is directly proportional to the total number of appearances they have made at the SCC between 2011 and 2025. The grey lines connecting a green dot and a red triangle represent a documented counsel-client relationship in a specific SCC case. A search bar was also equipped with this tool. When using the search bar to find and select a specific lawyer, the map highlights the selected one and all the institutions connected to it.

For instance, instead of blindly emailing lawyers representing large organizations, the clinic can now look at the “periphery” of this specific network. They might spot a red triangle (a lawyer) who has represented some organizations three or four times. This indicates the lawyer is experienced and trusted by previous players, but perhaps not as overwhelmed as the absolute top-tier litigators. The clinic can then approach this specific lawyer for a pro bono partnership.

3.2 The Jurisprudential Heatmap: Mapping Legal Territories

The next visualization is a Jurisprudential Heatmap. In this heatmap, the y-axis lists the most active NGOs, and the x-axis lists the various *Charter* sections. The intensity of the color (ranging from light colors to deep red) represents the frequency of intervention. A deep red square means that a specific NGO has intervened in that specific *Charter* section frequently.

See: [Code 3.2](#) at Jupyter Notebook *Final Code_Chong Tan.ipynb*

See full image: A2J_Dashboard_Counsels.png

By looking at these specific panels, an NGO could easily find the litigators who are proactive in the most popular *Charter* sections; an individual lawyer who wants to build their profile in s. 8 litigation can instantly see the top 10 NGOs that frequently intervene in that area, and then they can then offer their services to those specific organizations.

3.4 Practical Application Scenarios: The A2J User Journey

The following two scenarios illustrate how a clinic worker and a private lawyer might each use these tools in practice.

Scenario A: The Under-Resourced Legal Clinic

Imagine a small legal clinic based in Vancouver. They specialize in privacy rights and wish to intervene in an upcoming SCC case concerning s. 8. They have the expertise but lack the budget to hire external counsel.

Their user journey begins with the Strategic Dashboard. They locate the specific bar chart panel for “s. 8”. Instantly, they see the Top 10 NGOs that dominate this specific jurisprudential area, such as the BCCLA or the CCLA. Next, they transition to the Bipartite Network Map, using the search bar to highlight the BCCLA. It can be noticed that some lawyers sit on the periphery of the major hub but still have represented BCCLA 2-3 times. The clinic can now send a targeted email to these lawyers based on the verifiable data, saying that “*we see you have co-intervened with the BCCLA on Section 8 cases; we represent a similar privacy-rights constituency and are looking for pro bono co-counsel for an upcoming SCC case.*” That kind of specificity is far more likely to get a response.

Scenario B: The Individual Private Counsel

Conversely, consider a mid-level private lawyer in Toronto. They have resources, a passion for s. 15, and a desire to build their constitutional profile by doing *pro bono* work.

Their journey begins with the Jurisprudential Heatmap. They scan the columns for s. 15 and easily identify a lighter block corresponding to a smaller, regional equality rights NGO that has only intervened twice in the past decade. Using the Bipartite Network Map, the lawyer searches for this NGO and sees they only have one connected counsel, which indicates a potential capacity shortage. Thus, the lawyer can proactively reach out to them, offering to act as *pro bono* counsel for the

NGO's next SCC equality rights case.

IV. Filling A2J Gap and Critical Reflection

4.1 Repeat Players in *Charter* Intervenor

Although the SCC's intervention process is theoretically open to any organization with a sufficient interest in the proceeding, the data tells a different story in practice. The above visualized statistics, especially the resource map and dashboards, reveal that there are major institutional and individual players existing in the *Charter* intervention ecosystem.

In fact, this quantitative network map aligns with existing legal scholarship: Marc Galanter's¹² foundational theory of "Repeat Players"¹³ raised the argument that the legal system naturally favors institutional repeat players (those who litigate frequently) over one-shotters;¹⁴ in the Canadian context, empirical studies by scholars like F.L. Morton¹⁵ and Ian Brodie¹⁶ demonstrate that the SCC intervenor ecosystem is heavily dominated by a small and concentrated group of elite institutional repeat players and specialized law firms. This concentration highlights a critical A2J barrier. As Trevor Farrow emphasizes, A2J is not just about possessing a theoretical right; instead, it requires navigating a highly complex system and finding affordable, specialized legal representation.¹⁷ Farrow points out that the cost of legal services and the severe information asymmetry are the primary barriers for marginalized groups.¹⁸

4.2 Filling the Gap

For a small legal clinic, the threshold of SCC intervention is high. They may have a vital constitutional argument, but without a data-driven way to navigate the "Repeat Player" network and locate *pro bono* specialists, their access to the highest court remains entirely theoretical. The time and connections needed just to find the right lawyer is itself a barrier that this project tries to reduce.

Legal clinics often face severe funding shortages. As shown in Scenario A, clinics can use the network map to find targets quickly and can directly locate peripheral lawyers who are experienced but not overloaded. Similarly, as shown in Scenario B, private lawyers with resources can proactively find overlooked regional organizations.

4.3 Reflection on Risks and Limitations

There is an irony embedded in this tool's design. If it works so well that every under-resourced clinic in the country consults the same network map and reaches the same conclusion about who the top ten lawyers are, the result could be a further concentration of work among an already dominant

¹⁸ *Ibid* at 982.

group of litigators, not a broadening of the ecosystem. The tool risks replicating the very “Repeat Player” dynamic it is trying to disrupt. Although this is not an argument against the project, it does suggest that how the tool is used matters as much as the tool itself. Users need to be guided toward the periphery of the network, i.e., toward lawyers with several appearances rather than the major players. These lawyers are also the professionals who still have capacity to represent the under-resourced clinics.

Another critical limitation of this tool is the reliance on quantitation. The dataset records how many times a lawyer or NGO appeared at the SCC, but it captures nothing about the quality of their advocacy or their actual influence on the Court’s reasoning. For instance, a lawyer might appear ten times and lose every case, but a lawyer from a smaller province might appear once and shift the direction of Canadian constitutional law. Although ranking lawyers and NGOs by frequency of SCC appearance looks neutral, it is still just counting, which does not always matter. In fact, frequency is not an independent variable, because it reflects decades of accumulated advantage, including who had the institutional backing to appear repeatedly, who had the connections to get retained, and whose arguments the Court found credible enough to invite back. In Galanter’s terms, the network map does not merely show the Repeat Player hierarchy but also risks reinforcing it. It is possible that users may treat a high node count as a straightforward proxy for quality, which will potentially present historically contingent patterns of privilege as objective measures of expertise. In the context of *Charter* litigation, this risk is even higher than in ordinary litigation, since there is no way to see a success rate in intervention directly and thus no straightforward indicator of professional competence of a representative counsel. Furthermore, even though the Court finally accepts the position of the clinic in the judgment, it does not necessarily mean the lawyer presented exceptional advocacy skills – it may simply be a result of the unique contributions made by the clinic based on its practical experience.

A more distinct issue involves the nature of the underlying data itself. While the counsel-client relationships visualized in this network map are drawn entirely from public SCC dockets, there is a difference between information that is technically accessible and information that has been systematically aggregated, analyzed, and presented as a searchable ranking. A lawyer whose name appears in a handful of docket entries has not consented to being profiled as a “peripheral node” available for cold outreach. Whether this raises concerns under existing professional conduct rules is an open question, but it is one that any future public-facing deployment of this tool would need to address seriously.

4.4 Future Directions: Active Monitoring and Qualitative Assessment

To mitigate the limitations mentioned above, future iterations of this project will focus on two main directions.

First, the immediate next step is to transition this static data project into a proactive tool. I plan to develop a public web application called the “Charter Intervention Monitor”. This platform will feature an automated email subscription system, which actively alerts *pro bono* clinics and private counsel about newly granted SCC (and perhaps other courts like ONCA) cases that are open for intervention. Instead of passively waiting for clinics to search a database, this system pushes

opportunities directly to them.

Second, a much more ambitious future direction involves moving from measuring the quantity of interventions to evaluating their substantive quality and impact. My original concept explored using Large Language Models (LLMs) to perform semantic comparisons between intervenor factums and final SCC judgments. The goal was to algorithmically determine whose legal arguments were actually adopted by the Court. However, executing this vision presents massive methodological challenges. Proving causality in jurisprudence is incredibly difficult. Furthermore, an LLM could easily misclassify a court’s mere “discussion” of an argument as an “adoption” of that argument. Despite these hurdles, developing a robust NLP tool to measure true litigant influence remains the proposed next step.

V. Conclusion and Future Directions

The “A2J Charter Intervention Accelerator” started from a straightforward observation: the information needed to connect under-resourced clinics with willing private counsel already exists in the public record. It simply had not been organized in a way that made it usable. By scraping official SCC dockets directly, this project assembled a network map of Canadian constitutional litigation that is both empirically grounded and practically accessible.

It is true that data visualization cannot solve the funding crisis underlying the A2J problem. But the ambition of this project extends beyond any single tool. *Charter* litigation is resource-intensive at every stage, including identifying the right case to intervene in, finding counsel, drafting a factum that meets the SCC’s strict standards and attending court hearing. Each of these steps carries costs that disproportionately fall on the organizations and individuals least equipped to bear them. At this stage, the resource map addresses only the first of these barriers, i.e., lowering the search costs. Going forward, driven by the ongoing interest in constitutional litigation that existed before the project, the ultimate goal is to build on this foundation to develop a broader toolkit that reduces resource burden across each of these steps throughout the whole constitutional litigation process.

Appendix A: Methodological Details

Initially, this project attempted to use the HuggingFace a2aj/canadian-case-law dataset. The plan was to extract intervenor and counsel names from the judgment texts. However, testing showed critical accuracy issues. The core issue lies in the source text itself since the unstructured judgment texts simply lack complete metadata.

See: [Appendix A.1](#) at Jupyter Notebook *Final Code_Chong Tan.ipynb*

There are three main problems:

1. First, the source text misses lawyers who did not speak in court. For example, in *Quebec (Attorney General) v. Canada*,¹⁹ the AI found no counsel for the intervenor, Chief Firearms Officer since the dataset text only says “No one appeared” However, the official SCC docket confirms this party had registered counsel.
2. Second, the source text fails to distinguish between different legal roles. For the Intervenor in *Quebec Firearm* case, for the intervenor Coalition for Gun Control, the dataset text lists “Frédéric Langlois and Alain M. Gaulin” as the representing counsels together. It does not clarify that Langlois is the administrative Agent and Gaulin is the lead Counsel.
3. Third, combining different parts of the judgment does not solve the data gap, because the beginning of a judgment only lists lawyers who spoke in court, and the end of the judgment mostly lists law firm names. Thus, combining them still misses individual participation.

Because the original source text is fundamentally incomplete, this project pivoted to a custom web-scraping methodology targeting the official SCC dockets. I built a Python pipeline using the BeautifulSoup library to scrape the HTML tables from 402 SCC docket pages. After scraping the raw text, I used a Generative AI (“GenAI”) extraction tool to parse the relationships between organizations and lawyers.

See: [Appendix A.2](#) at Jupyter Notebook *Final Code_Chong Tan.ipynb*

Appendix B: Data Cleaning and Attached Datasets

Once extracted, rigorous data cleaning was required:

1. **Removing State Actors:** Entities like the “Attorney General of Ontario” intervene constantly. However, they are government bodies, not grassroots NGOs. Including them would heavily skew the network analysis. A Python function systematically removed all state actors.
2. **Normalizing Names:** An organization might be listed as “Canadian Civil Liberties Association” or “CCLA”. I built a normalization dictionary to merge these variations into single entities.
3. **Cleaning Professional Designations:** Lawyers frequently have professional designations attached to their names. I wrote a Regular Expression (Regex) script to systematically identify and remove titles like “Q.C.”, “K.C.”, or “Ad. E.”. This ensured the algorithm did not treat “John Doe, Q.C.” and “John Doe” as two different nodes.

¹⁹ [2015 SCC 14](#) [*Quebec Firearm*].

See: [Appendix B](#) at Jupyter Notebook *Final Code_Chong Tan.ipynb*

The complete, cleaned datasets generated from the web-scraping pipeline are attached to this report. They are designed to be ready for immediate use by A2J clinics or for future academic research.

- **A2J Intervenors Full Dataset.csv**: The raw, scraped docket data containing all 402 cases (and further revised as **A2J Intervenors Full Dataset FIXED.csv** – see details in *Appendix C*).
- **A2J Network Edges.csv**: The relationship data linking specific NGOs to specific individual counsel. This dataset powers the Bipartite Network Graph.
- **A2J Cases with Charter Sections.csv**: A dataset cross-referencing specific SCC cases with the exact *Charter* provisions litigated. This dataset powers the Jurisprudential Heatmap.
- **A2J NGO vs All Sections Matrix.csv**: This dataset powers the NGO dashboard.
- **A2J Counsels vs All Sections Matrix.csv**: This dataset powers the NGO dashboard.

Appendix C: Accuracy Validation and Programmatic Error Handling

C.1 Accuracy Check and Failure Mode

To verify the reliability of the extraction pipeline, I conducted an accuracy test by randomly selecting 30 cases across different years (2011–2025).

See: [Appendix C.1](#) at Jupyter Notebook *Final Code_Chong Tan.ipynb*

I manually cross-referenced the automated output against the official SCC online dockets. The pipeline achieved a 96.67% accuracy rate (29 out of 30 cases were perfectly extracted). The single discrepancy in the audit occurred in *Re First Nation Children*. In this case, the GenAI tool accurately identified the intervening organizations but defaulted to “None listed” for their counsel. It seems that when dealing with dockets that have an extraordinarily high number of intervenors (often over 30 parties), the GenAI reaches its context window limit or output token limit. To prevent crashing, the model abruptly truncates its output or defaults to generating empty values (“None listed”) for the entities at the end of the list.

Following this discovery, I conducted a comprehensive sweep of the entire 402-case dataset, which flagged a total of 6 cases with “None listed” value.²⁰ Manual verification of these 6 outliers revealed that the parties genuinely lacked counsel in 2 of these cases.²¹ However, the remaining four cases do indeed lack some information regarding the counsels and they are all cases with a large number of intervenors.

C.2 Current Solution

²⁰ I.e., *Imperial Oil v Jacques*, [2014 SCC 66](#) [*Imperial Oil*]; *Canada (Canadian Human Rights Commission) v Canada (Attorney General)*, [2018 SCC 31](#) [*Human Rights Commission*]; *Minister of Citizenship and Immigration v Alexander Vavilov*, [2018 CanLII 40807](#) [*Vavilov*]; *Attorney General of Quebec v Ronald Guérin*, [2016 CanLII 24871](#) [*Guérin*]; *References re Greenhouse Gas Pollution Pricing Act*, [2021 SCC 11](#) [*Re Greenhouse Gas*]; and *Re First Nation Children*, *Ibid*.

²¹ I.e., *Human Rights Commission*, *ibid*; and *Guérin*, *ibid*.

To ensure the absolute integrity of the visual analytics presented in Section III, I implemented a manual override for the affected 4 cases. The truncated counsel data were manually extracted from the SCC website and coded into the final dataset (and generated **A2J Intervenor Full Dataset FIXED.csv**). This manual correction guarantees 100% accuracy for the final network map and heatmap.

See: [Appendix C.2](#) at Jupyter Notebook *Final Code_Chong Tan.ipynb*

C.3 Proposed Future Strategies

Relying on manual overrides is not sustainable for a long-term automated tool. Future iterations of this project will implement programmatic safeguards to handle mega-cases:

1. **HTML String Chunking:** The Python script will be updated to automatically calculate the length of the scraped docket text. If the text exceeds a specific character limit, the script will split the text to feed the GenAI sequentially, and the results will be merged afterward.
2. **Upgraded AI Models:** Future versions will utilize newer LLMs with significantly larger context windows (such as models capable of handling 128k tokens or more) to process massive reference cases in a single prompt without truncation.

Appendix D: Disclosure of Generative AI Use

In accordance with the course policy, this appendix details the use of Generative AI in the development of this project and the writing of this final report.

AI System Used: Google Gemini (Gemini 3.1 Pro).

D.1 Code Generation and Data Engineering

- **Specific Parts:** I used Gemini to write the entirety of the Python code used in this project. This includes the web-scraping script (BeautifulSoup), the data cleaning functions (Regex), and the visualization code (NetworkX, PyVis, Seaborn).
 - **Prompts Used:** I provided Gemini with the HTML structure of the SCC dockets and prompted it with specific tasks, such as: *“scrape the intervenor and counsel names from this webpage, and remove professional titles like ‘Q.C.’”*

D.2 Literature Review and Summarization

- **Specific Parts:** I used Gemini to help read and summarize secondary sources to build the theoretical framework in Section I and IV.
 - **Prompts Used:** I uploaded academic articles (such as Alarie & Green’s paper) and prompted the AI: *“Summarize the main theoretical motivations for SCC interventions (accuracy, affiliation, acceptance) based on this text.”*

D.3 Text Generation and Editing

- **Specific Parts:** I used Gemini extensively to draft Section II and Appendices A-C of this report. This is because I have no computer science background, and I needed to prompt Gemini to generate the text based on the specific steps I took during the data engineering process.
 - **Prompts Used:** I discussed with Gemini during the whole programming process

and prompted such as: “*Summarize the engineering steps we took to correct the error and drafted what we did in natural language.*”

- **Structural Editing:** For the rest of the report (Sections I, III and IV), the core concepts, empirical findings, and personal reflections were entirely my own. However, I used Gemini as an advanced structural editor. I provided my original rough drafts and prompted the AI to revise them into an academic style.
 - **Prompts Used:** I fed my original drafts to the AI with prompts such as: “*Revise this section and ensure the tone is highly academic. Merge my empirical findings with Marc Galanter’s theory of Repeat Players.*”

Note that following the initial AI generation, I manually reviewed, extensively edited, and refined all textual outputs. This manual revision process was essential to verify factual accuracy, eliminate generic “AI-generated” phrasing, maintain my personal authorial voice, and ensure the nuances of the legal analysis accurately reflected my intentions. While Gemini was used to generate code, summarize texts, and edit the prose, I take full responsibility for all the content, data accuracy, empirical findings, and legal analyses submitted in this final report.
